Applications of four-body exponentially correlated functions

Mariusz Puchalski* and Krzysztof Pachucki†

Institute of Theoretical Physics, University of Warsaw, Hoża 69, 00-681 Warsaw, Poland

We demonstrate the applicability of four-body exponentially correlated functions for the accurate calculations of relativistic effects in lithium-like atoms and present results for matrix elements of various operators which involve negative powers of interparticle distances.

I. INTRODUCTION

In the accurate evaluation of atomic energy levels not only the nonrelativistic energy, but also relativistic and QED effects have to be calculated with the high precision. The only approach which consistently accounts for all corrections in small atomic systems is the one based on the expansion of the energy in the fine structure constant α

$$E = m \left[\alpha^2 \, \mathcal{E}^{(2)} + \alpha^4 \, \mathcal{E}^{(4)} + \alpha^5 \, \mathcal{E}^{(5)} + \alpha^6 \, \mathcal{E}^{(6)} + \alpha^7 \, \mathcal{E}^{(7)} + \ldots \right].$$
(1)

Each term in this expansion can be expressed as the expectation value of some effective Hamiltonian with the nonrelativistic wave function. Namely $\mathcal{E}^{(2)}$ is the nonrelativistic energy (in atomic units), $\mathcal{E}^{(4)}$ is the relativistic correction, which for states with the vanishing angular momentum is the expectation value of $H^{(4)}$ in Eq. (4). $\mathcal{E}^{(5)}$ and higher order corrections are expressed in terms of matrix elements of some more complicated operators. They have been calculated for low lying states of the helium atom and helium-like ions up to the order $m\,\alpha^6$ [1], and for the particularly important case of $2^3 P_J$ splitting up to the order $m\,\alpha^7$ [2]. One of the sources of this achievement was the flexibility of the explicitly correlated exponential basis set, which due to its correct analytic properties, makes possible accurate evaluation of matrix elements with complicated and singular operators.

In the case of the lithium atom and light lithium-like ions all corrections up to $\mathcal{E}^{(5)}$ have been accurately calculated [3–5], but not that of higher orders. The principal reason for the much slower progress for three-electron atoms is the difficulty in handling integrals with explicitly correlated functions. The commonly used explicitly correlated Gaussian functions do not have right analytic properties, for example they do not satisfy the cusp condition, and therefore cannot be used for the calculation of higher order relativistic corrections, like $\mathcal{E}^{(6)}$. Hylleraas basis functions have the right analytic behavior: the accuracy in solving the Schrödinger equation is the highest among all other basis functions, but it is difficult to handle Hylleraas integrals involving quadratic negative powers of two different interparticle distances. Such integrals appear in the evaluation of $\mathcal{E}^{(6)}$ and for this reason other basis functions have been investigated in the literature.

Zotev and Rebane in [6] were the first to apply exponentially correlated functions

$$\phi(\vec{r}_1, \vec{r}_2, \vec{r}_3) = e^{-\alpha_1 \, r_1 - \alpha_2 \, r_2 - \alpha_3 \, r_3 - \beta_1 \, r_{23} - \beta_2 \, r_{13} - \beta_3 \, r_{12}},$$
(2)

in variational calculations for Ps_2 and the other exotic molecules. They have found a simplified formula for matrix elements of the nonrelativistic Hamiltonian and presented numerical results of variational calculations with a few basis functions. In our recent paper [7] we presented an efficient algorithm for the evaluation of integrals involving powers of r_i and r_{ij}

$$g(n_1, n_2, n_3, n_4, n_5, n_6) = \int \frac{d^3 r_1}{4\pi} \int \frac{d^3 r_2}{4\pi} \int \frac{d^3 r_3}{4\pi}$$
$$r_1^{n_1-1} \, r_2^{n_2-1} \, r_3^{n_3-1} \, r_{23}^{n_4-1} \, r_{31}^{n_5-1} \, r_{12}^{n_6-1}$$
$$e^{-w_1 \, r_1 - w_2 \, r_2 - w_3 \, r_3 - u_1 \, r_{23} - u_2 \, r_{13} - u_3 \, r_{12}}$$
(3)

with n_a being nonnegative integers. It is based on recursion relations which start from the master Fromm-Hill integral [8, 9], where all $n_a = 0$. We have applied this algorithm to the variational calculations of the ground state of Li and Be$^+$ with up to 128 functions. The comparison of nonrelativistic energies with the ones obtained with much larger number of Hylleraas functions indicates that the exponential representation of the three-electron wave function is very efficient.

The class of integrals in Eq. (3) with nonnegative n_a is sufficient for nonrelativistic energies [6, 7]. However, it is not sufficient to calculate the leading relativistic effects described by Breit-Pauli Hamiltonian, which for S-states takes the form

$$H^{(4)} = \sum_a \left\{ -\frac{\vec{p}_a^4}{8\,m^3} + \frac{\pi\,Z\,\alpha}{2\,m^2} \delta^3(r_a) \right\}$$
$$+ \sum_{a>b} \left\{ \frac{\pi\,\alpha}{m^2} \delta^3(r_{ab}) - \frac{\alpha}{2\,m^2} p_a^i \left(\frac{\delta^{ij}}{r_{ab}} + \frac{r_{ab}^i \, r_{ab}^j}{r_{ab}^3} \right) p_b^j \right\}.$$
(4)

Its matrix elements involve an extended class of integrals with exactly one of n_a equal to -1, and all others are nonnegative, while that for leading QED effects involve integrals with $n_a = -2$. This is well known from calculations with Hylleraas basis functions, where all u_a in Eq. (3) are equal to zero. Hylleraas extended integrals of that kind have been extensively studied in [10–17] using multipole-type of expansions and recently by present authors using analytical recurrence approach [18, 19].

Both methods had been successfully applied in high-precision calculations of leading relativistic and QED corrections to the energy of lithiumlike systems [3, 19, 20]. There are no similar studies for exponentially correlated integrals to the best our knowledge, and for the first time we present them in this work.

In the calculation of relativistic and QED effects beyond leading order, $\mathcal{E}^{(6)}$ for example, another class of integrals appears with two quadratic inverse powers of interparticle distances. There are only few studies in the literature for three-electron Hylleraas integrals [12, 13, 17]. The algorithm by King [17] seems to be too slow for a large scale computation, where integrals with $\Omega = \sum_a n_a$ of order 30 have to be performed. The evaluation of these integrals is quite difficult with the recursion method and have not yet been worked out so far.

In the case of exponentially correlated integrals the problem seems to be even more severe, since the master integral with $u_a \neq 0$ is much more complicated. However, being able to optimize nonlinear parameters of each function independly, one does not need to use large powers of interparticle distances in the basis set. For S-states it is sufficient to use functions of the form (2). In such a case, having an analytical and thus accurate method for $g(n_1, n_2, n_3, n_4, n_5, n_6)$ with nonnegative n_a, inverse negative powers of the interparticle distance can be obtained by the numerical integration with respect to the corresponding parameter w_a or u_a. It however requires a good control of numerical accuracy of the master integral and of recursion relations in Eq. (10). The usage the higher precision arithmetic is essential in some critical areas of the integration. A key feature of our numerical integration strategy is the adapted quadrature, which allows one to get the high accuracy with a very small number of points.

We demonstrate our method on examples with expectation value of various operators on lithium ground state. Results obtained for matrix elements involving single $n_a = -1$ are compared to the most accurate ones obtained with the Hylleraas basis set. Good numerical convergence of results for matrix elements involving two negative powers, for example $1/(r_a^2 r_b^2)$, $1/(r_a^2 r_{ab}^2)$, $1/(r_{ab}^2 r_{bc}^2)$. indicate that this integration approach can be used for the calculation of higher order relativistic corrections, for example $m\,\alpha^6$ and $m\,\alpha^7$ effects in the hyperfine and fine structure of lithium-like systems.

II. CALCULATION OF INTEGRALS

A. Tetrahedral symmetry

An important property of integrals defined in Eq. (3) is the tetrahedral symmetry which is equivalent to the permutation group S_4. We can assign vertices 1,2,3 to the electrons and 0 to the nucleus as shown in Fig. (1), and to edges we assign u_a, w_a and n_a parameters of a given integral. The symmetry group S_4 corresponds to 24 renumbering of vertices 0,1,2, and 3, which means also a relevant change of parameters on the edges. The generated symmetry relations allow us to reduce the number of recurrence formulas for Slater integrals. It is necessary to derive only one recurrence scheme, and the formulas for the advancement in the other indices can then be

FIG. 1: Tetrahedron representing the integral from Eq. (2)

obtained by application of the S_4 symmetry.

B. Basic integrals

The evaluation method for $g(n_1, n_2, n_3, n_4, n_5, n_6)$ for the basis class with all nonnegative n_a was first presented by Harris in [21] and later by us in Ref. [7]. Here we present only a short summary, which is needed for the evaluation of the extended integrals. The master integral $g_0 \equiv g(0,0,0,0,0,0)$ satisfies the following differential equation

$$\sigma \frac{\partial g_0}{\partial w_1} + \frac{1}{2} \frac{\partial \sigma}{\partial w_1} g_0 + P = 0\,, \tag{5}$$

where the S_4 symmetric polynomial σ is of the form

$$
\begin{aligned}
\sigma =\ & u_1^2 u_2^2 w_3^2 + u_2^2 u_3^2 w_1^2 + u_1^2 u_3^2 w_2^2 + w_1^2 w_2^2 w_3^2 \\
& + u_1^2 w_1^2 (u_1^2 + w_1^2 - u_2^2 - u_3^2 - w_2^2 - w_3^2) \\
& + u_2^2 w_2^2 (u_2^2 + w_2^2 - u_1^2 - u_3^2 - w_1^2 - w_3^2) \\
& + u_3^2 w_3^2 (u_3^2 + w_3^2 - u_2^2 - u_1^2 - w_1^2 - w_2^2)\,,
\end{aligned} \tag{6}
$$

and function P is given by

$$
\begin{aligned}
P = \ & -u_1\, w_1\,[(u_1+w_2)^2 - u_3^2]\,\Gamma(0,0,-1; u_1+w_2, u_3, u_2+w_1) \\
& -u_1\, w_1\,[(u_1+u_3)^2 - w_2^2]\,\Gamma(0,0,-1; u_1+u_3, w_2, w_1+w_3) \\
& +[u_1^2\, w_1^2 + u_2^2\, w_2^2 - u_3^2\, w_3^2 + w_1\, w_2\,(u_1^2+u_2^2-w_3^2)]\,\Gamma(0,0,-1; w_1+w_2, w_3, u_1+u_2) \\
& +[u_1^2\, w_1^2 - u_2^2\, w_2^2 + u_3^2\, w_3^2 + w_1\, w_3\,(u_1^2+u_3^2-w_2^2)]\,\Gamma(0,0,-1; w_1+w_3, w_2, u_1+u_3) \\
& -[u_2\,(u_2+w_1)\,(u_1^2+u_3^2-w_2^2) - u_3^2\,(u_1^2+u_2^2-w_3^2)]\,\Gamma(0,0,-1; u_2+w_1, u_3, u_1+w_2) \\
& -[u_3\,(u_3+w_1)\,(u_1^2+u_2^2-w_3^2) - u_2^2\,(u_1^2+u_3^2-w_2^2)]\,\Gamma(0,0,-1; u_3+w_1, u_2, u_1+w_3) \\
& +w_1\,[w_2\,(u_1^2-u_2^2+w_3^2) + w_3\,(u_1^2+w_2^2-u_3^2)]\,\Gamma(0,0,-1; w_2+w_3, w_1, u_2+u_3) \\
& +w_1\,[u_2\,(u_1^2-w_2^2+u_3^2) + u_3\,(u_1^2+u_2^2-w_3^2)]\,\Gamma(0,0,-1; u_2+u_3, w_1, w_2+w_3),
\end{aligned} \tag{7}
$$

and where the two-electron integral Γ is

$$
\begin{aligned}
\Gamma(n_1, n_2, n_3, \alpha, \beta, \gamma) \equiv & \int \frac{d^3 r_1}{4\pi} \int \frac{d^3 r_2}{4\pi}\, r_1^{n_1-1}\, r_2^{n_2-1}\, r_{12}^{n_3-1} \\
& \times e^{-\alpha\, r_1 - \beta\, r_2 - \gamma\, r_{12}},
\end{aligned} \tag{8}
$$

$$
\Gamma(0,0,-1,\alpha,\beta,\gamma) = \frac{1}{(\alpha-\beta)\,(\alpha+\beta)} \ln\left(\frac{\gamma+\alpha}{\gamma+\beta}\right). \tag{9}
$$

The recurrence relations for the integrals g result from the differential equation (5) and can be written in a compact form as

$$
\sum_{i_1 \ldots i_6 = 0}^{n_1 \ldots n_6} \binom{n_1}{i_1}_{1/2} \cdots \binom{n_6}{i_6}_{1/2} \sigma(n_1-i_1, \ldots, n_6-i_6)\, g(i_1, \ldots, i_6)
$$

$$
= P(n_1-1, n_2, n_3, n_4, n_5, n_6), \tag{10}
$$

where we use a Newton-like symbol notation

$$
\binom{n}{0}_{1/2} = \frac{1}{2}, \qquad \binom{n}{n}_{1/2} = 1,
$$

$$
\binom{n}{i}_{1/2} = \binom{n-1}{i}_{1/2} + \binom{n-1}{i-1}_{1/2}, \tag{11}
$$

and

$$
P(n_1, n_2, n_3, n_4, n_5, n_6) =
$$
$$
(-1)^{n_1 + \ldots + n_6} \frac{\partial^{n_1}}{\partial w_1^{n_1}} \cdots \frac{\partial^{n_6}}{\partial u_3^{n_6}}\, P, \tag{12}
$$

$$
\sigma(n_1, n_2, n_3, n_4, n_5, n_6) =
$$
$$
(-1)^{n_1 + \ldots + n_6} \frac{\partial^{n_1}}{\partial w_1^{n_1}} \cdots \frac{\partial^{n_6}}{\partial u_3^{n_6}}\, \sigma. \tag{13}
$$

The relation (10) allows one to express the integral $g(n_1, .., n_6)$ with positive index n_1 through g-integrals with smaller nonnegative indices. Derivatives of polynomials in $P(n_1, n_2, n_3, n_4, n_5, n_6)$ and $\sigma(n_1, n_2, n_3, n_4, n_5, n_6)$ are calculated explicitly. The master integral $g(0,0,0,0,0,0)$ and the two-electron integrals Γ are needed to start the evaluation of $g(n_1, n_2, n_3, n_4, n_5, n_6)$ from recursion relations. For $g(0,0,0,0,0,0)$ we implemented the formula of Fromm-Hill [8] in the version improved by Harris [9]. The calculation of the two-electron Γ functions has been described in detail in Refs. [22–24]. In Eq. (10) the parameter w_1 is distinguished on the right-hand side. We can define the same recurrence relations with other variables w_a, u_a from expressions (7), (10), and (13) by applying the tetrahedral symmetry.

The proposed recurrence scheme allows us to calculate integrals from higher shells Ω very efficiently. In Table I we present values in two reference points introduced by Fromm and Hill in Ref. [8]. These are the standard reference point (SRP) $w_a = u_a = 1$ where $\sigma = -2$ and the auxiliary reference point (ARP) $w_a = 1$, $u_a = 0$ with $\sigma = 1$. Values for the last one can be compared to the known Hylleraas results. All presented digits are significant, which confirms the very good stability of the recursions at least at these reference points.

The integrals $g(n_1, n_2, n_3, n_4, n_5, n_6)$ with σ is close to zero are difficult to evaluate because the recurrence relations are numerically unstable. Following Harris' studies on the master integral $g(0,0,0,0,0,0)$ in Ref. [9], we considered $w_a = 1$, $u_a = \alpha$ close to $\alpha = 3^{-1/2}$ where σ is exactly equal to zero. As an example we present in Table II values for

$g(1,1,1,1,1,1)$ which needs six evaluations of recursions (10). Close to the critical point $\sigma = 0$, we used Bailey's multiprecision library [25]. We control the number of significant digits by dynamical estimating and adjusting the appropriate precision of the arithmetic. As presented in Table II, we can approach the critical point $\sigma = 0$ as close as we need for practical purposes. This strategy of course slows down the algorithm significantly, but in practical applications the parameters close to the critical point $\sigma = 0$ are very rare. This strategy of controlling precision in the region of instabilities allows one to cross $\sigma = 0$ points in the minimization of the nonrelativistic energy. In Table III we present results for nonrelativistic energies for the ground state of Li obtained with global minimization of all nonlinear parameters in the basis length of $N = 128, 256, 512$ respectively. The achieved precision is much higher than that from similar number of Hylleraas functions.

C. Extended integrals

In this section we present an algorithm for calculations of extended integrals with $1/r_a^2$ or $1/r_{ab}^2$ factors in Eq (3). This means that some of indices in $g(n_1, n_2, n_3, n_4, n_5, n_6)$ are equal to -1. Fully correlated exponent in Eq. (3) gives the opportunity to obtain extended integrals by using either a single integration over w_a or u_a i.e.

$$g(n_1, n_2, n_3, -1, n_5, n_6) = \int_{u_1}^{\infty} du_1\, g(n_1, n_2, n_3, 0, n_5, n_6),$$

(14)

$g(15, 0, 0, -1, 0, 0)$	$4.364\,311\,343\,749\,328\,364\,240\,301\,511\,7\ 10^{10}$	$6.183\,347\,201\,330\,971\,024\,067\,326\,468\,8\ 10^{3}$

or a double integration i.e.

$$
g(n_1, -1, n_3, -1, n_5, n_6) = \int_{u_1}^{\infty} d\,u_1 \int_{w_2}^{\infty} dw_2\, g(n_1, 0, n_3, 0, n_5, n_6).
$$
(15)

The adaptive increase of the arithmetic precision close to critical points $\sigma = 0$ is necessary here for the precise evaluation of $g(n_1, n_2, n_3, n_4, n_5, n_6)$. Moreover, one is able to perform accurately this integration by using N-point generalized Gaussian quadrature with logarithmic end-point singularity [26]

$$
\begin{aligned}
I &= \int_0^1 dx \left[W_1(x) + \ln(x)\, W_2(x) \right] \\
&\approx \sum_{i=1}^{N} w_i \left[W_1(x_i) + \ln(x_i)\, W_2(x_i) \right],
\end{aligned}
$$
(16)

where W_i are regular functions on the interval $(0, 1)$. This quadrature becomes exact for W_i being polynomials of maximal degree $N - 1$, and the example of 30 point quadrature, which is used through out this paper for calculation of mean values, is presented in Appendix A.

If integration variable u in Eq. (14) is mapped into the interval $(0, 1)$ by the following change of variable

$$
\int_0^{\infty} du\, f(u) = \int_0^1 dx\, \frac{1}{x^2}\, f\left(\frac{1}{x} - 1 \right)
$$
(17)

then the quadrature with logarithmic end-point singularity is sufficient for one-dimensional integrals in Eq. (14), where $N = 30$ quadrature allows one to obtain about 30 significant digits as shown in Table IV.

The presented values for integrals are obtained at ARP and SRP points. Some of them can be found in the literature, for example $g(2, 2, 2, -1, 2, 2)$ at ARP point [17, 18], which corresponds to a Hylleraas type of integral. Perfect agreement with those results, demonstrates high accuracy is achieved for the extended integrals. The proposed evaluation method fully relies on properties of the recurrence algorithm for basis integrals, which must be very stable on the integration path over the corresponding parameter.

In comparison to the one-dimensional integral in Eq. (14), the convergence of two-dimensional integral Eq. (15) with respect to the number of integration points is much worse. For this reason we use a slightly different mapping into $(0, 1)$ intervals, which is

$$
\begin{aligned}
\int_0^{\infty} du \int_0^{\infty} dw\, f(u, w) = \\
\int_0^1 dx \int_0^1 dy\, \frac{4}{x^3\, y^3}\, f\left(\frac{1}{x^2} - 1, \frac{1}{y^2} - 1 \right).
\end{aligned}
$$
(18)

The numerical convergence of the integral in Eq. (15) is the worst for the case $n_3 = 0$, where the leading asymptotics includes a square of the logarithm. For $n_3 > 0$ convergence improves significantly. The use of Gaussian quadrature adapted to logarithmic end-point singularity with 30 points is enough for practical applications. In Table V we presented numerical values for $g(n_1, -1, n_3, -1, n_5, n_6)$ in ARP and SRP reference points with the accuracy of 10^{-16}. In the case of $n_3 = 0$ they have been obtained with 60 point quadrature. It is possible to obtain even higher accuracy for $n_3 > 0$, but further improvement for $n_3 = 0$ requires a more sophisticated integration strategy. There are no such problems with integration involving parameters which are attached to opposite edges of the tetrahedron, i.e. $g(-1, n_2, n_3, -1, n_5, n_6)$, see Fig. 1, so this case of integral in Eq. (14) with $n_3 = 0$ is the one which limits accuracy of mean values.

D. Expectation values

The basis class of integrals ($n_i \geq 0$) and the class with the one index equal to -1 is sufficient for all mean values of operators like those in the Breit-Pauli Hamiltonian, Eq. (4). As an example we demonstrate their evaluation for the lithium ground state. In Table VI we present results for the Dirac δ functions using the Drachman formulae [27]

$$\langle 4\pi\delta^3(r_a)\rangle = \left\langle \frac{4}{r_a}(E_0 - V)\right\rangle - \sum_c \left\langle \vec{\nabla}_c\phi \left| \frac{2}{r_a} \right| \vec{\nabla}_c\phi \right\rangle,$$
(19)

$$\langle 4\pi\delta^3(r_{ab})\rangle = \left\langle \frac{2}{r_{ab}}(E_0 - V)\right\rangle - \sum_c \left\langle \vec{\nabla}_c\phi \left| \frac{1}{r_{ab}} \right| \vec{\nabla}_c\phi \right\rangle,$$
(20)

where V is a total interaction potential. The similar prescriptions can be used for p_a^4 operator

$$\left\langle \sum_a p_a^4 \right\rangle = 4\langle (E_0 - V)^2\rangle - \sum_{b>c}\langle \nabla_b^2\phi | \nabla_c^2\phi\rangle.$$
(21)

In Table VII we present numerical values for typical operators in higher order perturbation theory i.e. $m\alpha^6$ correction

These forms significantly improve accuracy of numerical results in comparison to direct calculations, like those presented in our previous paper [7], see Table VI. Nevertheless, with 256 functions they are about two digits less accurate than the most precise results obtained from 9564 Hylleraas basis functions. These Hyleraas results are slightly more accurate than those in [19] due to better optimization of the nonrelativistic wave function.

As we have noticed, for the nonrelativistic energy one needs approximately six times smaller basis set of exponentially correlated functions as compared to Hylleraas functions to obtain similar accuracy, and the same is confirmed for the mean values of operators. The achieved accuracy is limited only by the number of basis functions, which nevertheless should be well optimized. In practice it demands more computing power than we used up to now and a parallel version of the algorithm would be necessary for optimization of a large number of Slater functions.

to the energy. For these operators we need to use all the discussed classes of integrals. $g(n_1, n_2, n_3, n_4, n_5, n_6)$ integrals

with two parameters equal to -1 are obtained with double integration with 30×30 points and all the presented digits in Table VII are accurate for the corresponding approximate wave function.

III. SUMMARY

Our primary motivation for developing explicitly correlated exponential basis set is the efficient representation of the wave function in a small number of basis functions. We applied it for the accurate numerical calculation of expectation values of some operators corresponding to higher order relativistic and QED effects. They involve integrals with quadratic inverse powers of at least two interparticle distances, which are the most difficult in the evaluation. Using this compact and very flexible correlated exponential basis set, we are aiming to determine $m\,\alpha^6$ and $m\,\alpha^7$ effects in the hyperfine and fine structure of lithium-like systems, which have not been investigated so far.

Appendix A: Weights and nodes of generalized Gaussian quadrature with logarithmic end-point singularity

We present here a set of 30 nodes and corresponding weights for generalized Gaussian quadrature with logarithmic end-point singularity [26], which was obtained using the algorithm described in Appendix A of Ref. [19]. We used these quadrature points for numerical integration of extended integrals in Tables IV, VI, and VII.

TABLE VIII: Weights and nodes of generalized Gaussian quadrature with logarithmic end-point singularity
